Things You Need to Know

- There is a lot of material in these slides
- Far more than can be covered in 1 hour
- Provided as reference so you can explore more deeply
- I will highlight things I believe you need to understand
- Emphasis will be on showing it in action
- A whitepaper/red-piece is under construction

Preface

- Examples built and run using ClefOS 7.5.1804
 - CentOS Clone with name change
 - Available for z Systems
- However, as we will see this is irrelevant
- All OpenShift Origin containers are available on dockerhub under the clefos repository: <u>https://hub.docker.com/u/clefos/dashboard/</u>

Docker – underlying technologies

©®®= 4

Things You Need to Know

- Docker and other container-based technologies rely on Linux kernel APIs to provide isolation and infrastructure
 - Cgroups
 - Copy-on-write
- A daemon is responsible for doing the work via a set of APIs (OCI-compliant)
- Storage is ephemeral unless otherwise specified

pyright@ by SHARE Association Except where otherwise noted, this work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivs 3.0 license. http://creativecommons.org/licenses/by-nc-nd/3.0/

Skip

What is Docker

- An open source project to pack, ship and run any application as a lightweight container
- Container: self-contained receptacle
 - Filesystem
 - Apps
 - Static data
 - Network

Skip

cgroups...

- A kernel feature that limits, accounts for, and isolates the resource of a collection of processes
- Similar to processes:
 - They are hierarchical
 - Child cgroups inherit certain attributes from their parent cgroup
- Difference: multiple cgroup hierarchies

- Can span multiple "subsystems"
 - blkio —sets limits on input/output access to and from block
 - cpu —uses the scheduler to provide cgroup tasks access to the CPU
 - cpuacct —generates automatic reports on CPU resources used by tasks in a cgroup.

- Can span multiple "subsystems"
 - cpuset —assigns individual CPUs (on a multicore system) and memory
 - devices —allows or denies access to devices by tasks in a cgroup
 - freezer —suspends or resumes tasks in a cgroup

- Can span multiple "subsystems"
 - memory —sets limits on memory use by tasks in a cgroup, & generates automatic reports on memory
 - net_cls —tags network packets with a class identifier (classid) that allows the Linux traffic controller (tc) to identify packets originating from a particular cgroup task.

- Can span multiple "subsystems"
 - net_prio —provides a way to dynamically set the priority of network traffic per network interface
 - ns the namespace subsystem

Namespaces...

- CLONE_NEWIPC: IPC Namespaces: SystemV IPC and POSIX Message Queues can be isolated.
- CLONE_NEWPID: PID Namespaces: PIDs are isolated, meaning that a virtual PID inside of the namespace can conflict with a PID outside of the namespace. PIDs inside the namespace will be mapped to other PIDs outside of the namespace. The first PID inside the namespace will be '1' which outside of the namespace is assigned to init

Copyright© by SHARE Association Except where otherwise noted, this work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivs 3.0 license. http://creativecommons.org/licenses/by-nc-nd/3.0/

- same ports within namespaces, and "duplicate" virtual interfaces can be created.
 CLONE NEWNS: Mount Namespaces. We have the ability to isolate mount points as they appear to processes. Using mount
 - namespaces, we can achieve similar functionality to chroot() however with improved security.

...Namespaces

- CLONE_NEWUTS: UTS Namespaces. This namespaces primary purpose is to isolate the hostname and NIS name.
- CLONE_NEWUSER: User Namespaces. Here, user and group IDs are different inside and outside of namespaces and can be duplicated.

Copyright© by SHARE Association Except where otherwise noted, this work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivs 3.0 license. http://creativecommons.org/licenses/by-nc-nd/3.0/

©•\$=

Copy-on-Write

- Allows Docker to instantiate containers very quickly
- Instead of having to make full copies of the which files comprise a container, it can use "pointers" back to existing files
- Containers are easily "linked" (or "stacked" or "layered") to other containers

Copyright© by SHARE Association Except where otherwise noted, this work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivs 3.0 license. http://creativecommons.org/licenses/by-nc-nd/3.0/

Docker Registry (optional)

- A stateless, highly scalable server-side application that stores and distributes Docker images
- Enables:
 - Tight control where images are stored
 - Full ownership of distribution pipeline
 - Integration of image storage & distribution into an in-house development workflow

Copyright© by SHARE Association Except where otherwise noted, this work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivs 3.0 license. http://creativecommons.org/licenses/by-nc-nd/3.0/

Docker Daemon

- Manages containers
 - Creates volumes
 - Starts/stops containers

docker daemon -H tcp://0.0.0.0:4243 -H
unix:///var/run/docker.sock

OR systemctl enable docker systemctl start docker

ht© by SHARE Association Except where otherwise noted, this work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivs 3.0 license. http://creativecommons.org/licenses/by-nc-nd/3.0/

Docker – Building Containers

©®®= 18

Things You Need to Know

- Everything starts with a base image
- Dockerfiles are text files with recipes for building images based on another image
- Images are held in a registry
- Dockerhub is the public repository
- There are official images that you can trust
- Otherwise... Buyer beware
- Images are run in containers which may be linked or grouped

Skip

©••\$=

Creating a Starter System

- Base image: containers built from it or descendants
- Create a chroot-like environment
 - File system including /dev
 - yum install packages
 - Trim unwanted stuff
 - Create tar ball
 - Import to Docker
- "Official Images" Those accepted by Docker
 - · ClefOS is now an official image

The Dockerfile

- A recipe for building a container
- Build from an existing container
- Install requirements
- Define network and volume requirements
- Specify command to run on startup

pyright® by SHARE Association Except where otherwise noted, this work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivs 3.0 license, http://creativecommons.org/licenses/by-nc-nd/3.0/

Things You Need to Know

- OpenShift is a layer on top of Kubernetes
 - OS v3.xx based on K8 v1.xx
- K8 is a manager of containerized apps across a set of containers and/or hosts
- Concepts of master node, infrastructure node, and compute node
- Provides registry, router, users, groups, projects, builds, templates
- Installs via ansible playbooks which takes care of a lot of the minutiae

What is OpenShift?

• OpenShift is a layer on top of:

3 7

- Docker provides the abstraction for Linux-based lightweight container images
- Kubernetes provides cluster management & orchestrates containers on multiple hosts
- OpenShift Origin is the Community Edition

Kubernetes

3 8

- Manages containerized applications across a set of containers or hosts
- Provides mechanisms for deployment, maintenance, and application-scaling

Kubernetes Components

Component	Description
API Server	Validates and configures the data for pods, services, and replication controllers. It also assigns pods to nodes and synchronizes pod information with service configuration
etcd	Stores the persistent master state while other components watch etcd for changes to bring themselves into the desired state
Controller Manager	Watches etcd for changes to replication controller objects and then uses the API to enforce the desired state
HAProxy	Option to balance load between API master endpoints.

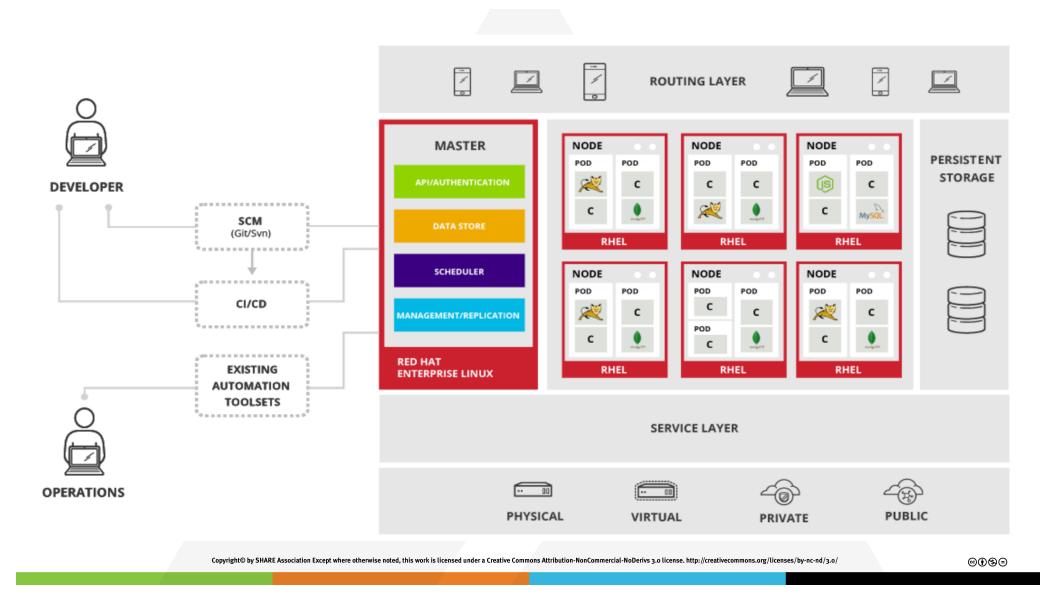

What is OpenShift

• OpenShift Origin adds:

٥

- Source code management, builds, and deployments for developers
- Managing and promoting images at scale as they flow through your system
- Application management at scale
- Team and user tracking for organizing a large developer organization
- Networking infrastructure that supports the cluster

OpenShift Core

- Containers & images are the building blocks for deploying applications
- Pods & services allow for containers to communicate with each other and proxy connections
- Projects and users provide the space and means for communities to organize and manage their content together

OpenShift Core

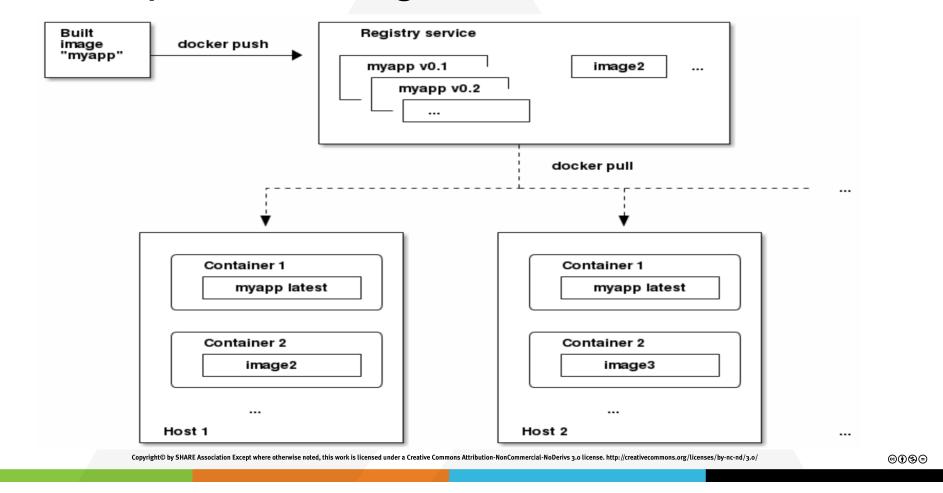

- Builds & image streams allow you to build working images and react to new images
- Deployments add expanded support for the development and deployment lifecycle
- Routes announce your service to the world
- Templates allow for many objects to be created at once based on customized parameters.

OpenShift Registries

- A service for storing and retrieving Docker-formatted container images
- A registry contains a collection of one or more image repositories
- Each image repository contains one or more tagged images

OpenShift Registries

SHARE

EDUCATE > NETWORK > INFLUENCE

OpenShift Pods

- One or more containers deployed together on one host
- The smallest compute unit that can be defined, deployed, and managed.
- Rough equivalent of a machine instance to a container
- Each pod is allocated its own internal IP address

OpenShift Pods

- Containers within pods can share their local storage and networking.
- Pods have a lifecycle: they are defined, assigned to run on a node, then run until their container(s) exit or are Largely immutable: changes cannot be made to a pod definition while it is running
- Changes result in termination & recreation

OpenShift Users

- Interaction with OpenShift Origin is associated with a user
- Users may be placed into groups
- A user object represents an actor which may be granted permissions in the system by adding roles to them or to their groups:
 - Regular Users
 - System Users
 - Service Accounts

OpenShift Projects

- A Kubernetes namespace with additional annotations,
- The central vehicle by which access to resources for regular users is managed
- Allows a community of users to organize and manage their content in isolation from other communities.
- Users must be given access to projects by administrators

OpenShift Builds

- A build is the process of transforming input parameters into a resulting object.
- Transform input parameters or source code into a runnable image
- A BuildConfig object is the definition of the entire build process.
- OpenShift Origin creates Docker-formatted containers from build images and pushing them to a container registry

- Pods may run on any node
 - Local storage insufficient
- NFS, AWS, iSCSI, GlusterFS, CephFS, or SCSI (zFCP) [and more]
- Kubernetes < 1.8 (OpenShift < 3.8) has limitation for SCSI

OpenShift Replication and Jobstein Etwork INFLUENCE

- Replication Controllers
 - Ensures that a specified number of replicas of a pod are running at all times
- Jobs
 - Similar to replications but designed for one-time pods

OpenShift Deployments

- Provides the ability to transition from an existing deployment of an image to a new one
- Defines hooks to be run before or after creating the replication controller
- When triggered a deployer-pod manages the deployment including scaling down the old replication controller, scaling up the new one, and running hooks
- Triggers may include such things such as a new image becoming available

OpenShift Templates

- Describe a set of objects that can be parameterized and processed to produce a list of objects for creation by OpenShift Origin
- The objects to create can include anything that users have permission to create within a project, e.g. services, build configurations, and deployment configurations.
- May also define a set of labels to apply to every object defined in the template

OpenShift Origin – Demonstration

Things You Need to Know

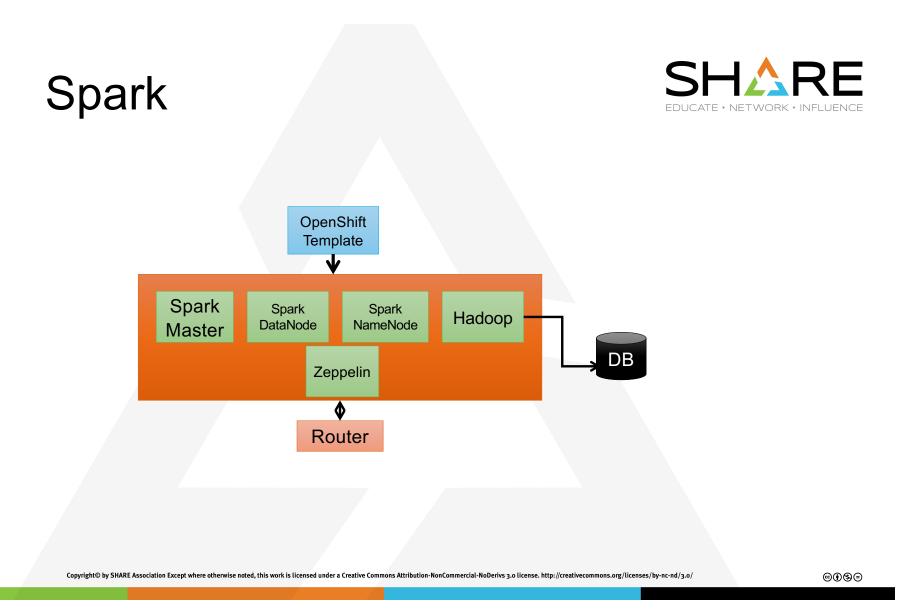

- Demo system is an "all-in-one"
 - 1 virtual machine running
 - Master
 - Infrastructure
 - Compute
- Live demos are unpredictable
- Point your browsers to <u>https://okcd-</u> master.sinenomine.net:8443
 - sna/test or admin/sna

Demo Time

- Using the GUI
- Using the CLI
- Examining the registry
- Simple on pod application
- Source-to-Image application (MLB)
 - JBOSS (Wildfly) & MongoDB
- Orchestration of multiple pods
 - Spark, Hadoop, & Zeppelin

* Name

hello-route

A unique name for the route within the project.

Hostname

148.100.42.153

Public hostname for the route. If not specified, a hostname is generated. The hostname can't be changed after the route is created.

Path

/hello

Path that the router watches to route traffic to the service.

* Service

hello-openshift

Service to route to.

Split traffic across multiple services

Target Port

8080 → 8080 (TCP)

Target port for traffic.

Secure route

Routes can be secured using several TLS termination types for serving certificates.
